

8.5

A thick wood slab spread a flame downward at 0.1 mm/s; the slab was initially at 20 C. If the slab were preheated to 100 C, what is the spread rate? Assume  $T_{ig}=450\text{C}$ .

$$V_p := 0.1 \cdot 10^{-3} \quad T_s := 20 \quad T_{ig} := 450$$

$$\text{phibyrhoc} := V_p \cdot (T_{ig} - T_s)^2 \quad \text{phibyrhoc} = 18.49$$

$$T_{s1} := 100 \quad V_p := \frac{\text{phibyrhoc}}{(T_{ig} - T_{s1})^2} \quad V_p = 1.509 \times 10^{-4}$$

There is a 50% increase in the flame spread rate associated with preheating the wood sample. Note that we have assumed that there is no change in the kinetics which may not be accurate.
